## Problem

- I/O analysis often rely on heuristics and I/O analysis tools are built on top of those heuristics
- I/O analysis tools can benefit from transitioning from heuristics-based approaches towards trace-data-driven decision-making
- According to our findings, data-driven decision-making can be helpful in two areas:
  - Reducing the search space
    - DXT and Recorder offer highly detailed traces which comes at the cost of significantly larger trace sizes
  - Data-driven identification of problematic I/O accesses
    - I/O analysis involves querying I/O traces to identify issues by applying heuristics
    - While heuristics accumulated through extensive studies are highly valuable, the evolving nature of workloads necessitates new studies to generate new heuristics
      - e.g., deep learning applications, async checkpointing

### Motivation

1/24/2024

- The following is from DLIO Benchmark for a TensorFlow workload with NumPy arrays
  - 5TB in size, accesses 5376 files of 132MB in size, 4 read threads, 1000 epoch = multimillion I/O accesses
- Analyzing this data from a time-based perspective would not reveal that the first thread doesn't do any I/O, unlike the other threads

### Multi-Perspective Views

- So, reality is often more complex!
- Multi-perspective views enable us to look at the same trace data from multiple viewpoints
- This helps us not only to reduce the amount of data analyzed per view, but also to identify problematic I/O accesses more accurately

#### Multi-Perspective Views

- As demonstrated, large-scale workflows may accumulate well over 1 billion I/O accesses
  - Our convergence analysis reduces the search space significantly while retaining the most critical I/O accesses
- Multi-perspective views include time-, fileand process-based views
  - The figure shows that certain problematic I/O accesses can only be identified using specific views
- This demonstrates that the trace data itself can be used to pinpoint the most critical issues

Thank you!
